

## PROBLEM SHEET 4

Alex Kavvos

The following questions are about the simply-typed  $\lambda$ -calculus (STLC).

1. Draw derivations that evidence the following typing judgements.

$$(i) \quad x : \text{Str} + (\text{Str} \times \text{Num}) \vdash \text{case}(x; y. y; z. \pi_1(z)) : \text{Str}$$

$$(ii) \quad \vdash \lambda x : \text{Str} + \text{Num}. \text{case}(x; y. \text{inr}(y); z. \text{inl}(z)) : \text{Str} + \text{Num} \rightarrow \text{Num} + \text{Str}$$

$$(iii) \quad f : \text{Num} \times \text{Str} \rightarrow \text{Num}, x : \text{Str} \vdash f(\langle \text{num}[0], x \rangle) : \text{Num}$$

2. Write down transition sequences that reduce the following terms to values.

$$(i) \quad \text{case}(\text{inr}(\langle \text{str}[\text{'hi'}], \text{num}[0] \rangle); y. y; z. \pi_1(z))$$

$$(ii) \quad (\lambda x : \text{Str} + \text{Num}. \text{case}(x; y. \text{inr}(y); z. \text{inl}(z)))(\text{inl}(\text{num}[0]))$$

$$(iii) \quad (\lambda z. \pi_1(z))(\langle \text{num}[0], \text{str}[\text{'hi'}] \rangle)$$

**Solution:**

(i)

$$\begin{aligned} \text{case}(\text{inr}(\langle \text{str}[\text{'hi'}], \text{num}[0] \rangle); y. y; z. \pi_1(z)) &\mapsto \pi_1(\langle \text{str}[\text{'hi'}], \text{num}[0] \rangle) \\ &\mapsto \text{str}[\text{'hi'}] \end{aligned}$$

(ii)

$$\begin{aligned} (\lambda x : \text{Str} + \text{Num}. \text{case}(x; y. \text{inr}(y); z. \text{inl}(z)))(\text{inl}(\text{num}[0])) &\mapsto \text{case}(\text{inl}(\text{num}[0]); y. \text{inr}(y); z. \text{inl}(z)) \\ &\mapsto \text{inr}(\text{num}[0]) \end{aligned}$$

$$(iii) \quad (\lambda z. \pi_1(z))(\langle \text{num}[0], \text{str}[\text{'hi'}] \rangle) \mapsto \pi_1(\langle \text{num}[0], \text{str}[\text{'hi'}] \rangle) \mapsto \text{num}[0]$$

3. This question is about modelling the following Haskell data type in the simply-typed  $\lambda$ -calculus.

**data** MaybeString = Nothing | Just String

Intuitively, we expect this data type MaybeStr to have the following typing rules.

$$\begin{array}{c} \text{NOTHING} \\ \hline \Gamma \vdash \text{Nothing} : \text{MaybeStr} \end{array} \qquad \begin{array}{c} \text{JUST} \\ \Gamma \vdash e : \text{Str} \\ \hline \Gamma \vdash \text{Just}(e) : \text{MaybeStr} \end{array}$$

$$\begin{array}{c} \text{MATCH} \\ \Gamma \vdash e : \text{MaybeStr} \quad \Gamma \vdash e_n : \tau \quad \Gamma, x : \text{Str} \vdash e_j : \tau \\ \hline \Gamma \vdash \text{match}(e; e_n; x. e_j) : \tau \end{array}$$

The first term represents **Nothing**, and the second term that represents **Just**  $e$ , where  $e :: \text{String}$ .

The third term performs **pattern matching**. It first examines  $e$ : if that is a **Nothing** it returns  $e_n$ ; if it is a **Just**( $e$ ) with  $e : \text{Str}$ , it substitutes  $e$  for  $x$  in  $e_j$ . Thus **match**( $-; e_n; x. e_j$ ) corresponds to the definition

```
f Nothing = e_n
f (Just x) = e_j -- this clause can use the variable x :: String
```

- (i) Write down a representation of this type in the STLC. [Hint: use 1.]
- (ii) Show that the three rules **NOTHING**, **JUST** and **MATCH** above are **definable**. That is, show the terms **Nothing**, **Just(*e*)** and **match(*e*; *e<sub>n</sub>*; *x*. *e<sub>s</sub>*)** can be expanded into some term of the STLC, which is such that the typing rules are **derivable** if we assume that weakening is a typing rule of the system.

**Solution:**

(i)  $1 + \text{Str}$

(ii) Let

$$\begin{aligned}\text{Nothing} &\stackrel{\text{def}}{=} \text{inl}(\langle \rangle) \\ \text{Just}(x) &\stackrel{\text{def}}{=} \text{inr}(x) \\ \text{match}(e; e_n; x. e_s) &\stackrel{\text{def}}{=} \text{case}(e; \text{inl}(y). e_n; \text{inr}(x). e_s)\end{aligned}$$

Here is the proof that the typing rules given above are derivable.

$$\begin{array}{c} \frac{}{\Gamma \vdash \langle \rangle : 1} \text{UNIT} \\ \hline \Gamma \vdash \text{Nothing} \stackrel{\text{def}}{=} \text{inl}(\langle \rangle) : 1 + \text{Str} \quad \text{INL} \end{array} \qquad \frac{}{\Gamma \vdash x : \text{Str}} \text{UNIT} \\ \hline \Gamma \vdash \text{Just}(x) \stackrel{\text{def}}{=} \text{inl}(x) : 1 + \text{Str} \quad \text{INR}$$

$$\frac{\frac{}{\Gamma \vdash e : 1 + \text{Str}} \quad \frac{\frac{}{\Gamma \vdash e_n : \tau}}{\Gamma, y : 1 \vdash e_n : \tau} \text{WK} \quad \frac{}{\Gamma, x : \text{Str} \vdash e_s : \tau}}{\Gamma \vdash \text{match}(e; e_n; x. e_s) \stackrel{\text{def}}{=} \text{case}(e; y. e_n; x. e_s) : \tau} \text{CASE}$$

The rule WK corresponds to the assumption that weakening is a primitive rule of the system. Of course, weakening is not a rule of the STLC, but it is admissible: given a derivation of  $\Gamma \vdash e_n : \tau$  we can construct a derivation of  $\Gamma, y : 1 \vdash e_n : \tau$  (this requires inductive proof).

4. (\*) Prove progress and preservation for the **constants-and-functions** fragment of the STLC.

[Hint: The constants-and-function fragment of the STLC is an extension to the language of numbers and strings: we reached it by *adding* the rules for function types. Thus, to establish these theorems **you only need to show them for the new rules**, as last week's proofs cover the rest!]

Do this in steps. First extend the inversion, substitution, and canonical form lemmas to function types. You will need weakening; you may assume it, but you can also prove it if you feel like it. Then, prove preservation and progress. Pretend there are no products or sums throughout.]

**Solution:**

**Claim 1** (Inversion). Suppose  $\Gamma \vdash e : \tau$ .

- If  $e = \lambda x : \sigma. e'$  then  $\tau = \sigma \rightarrow \tau'$  for some type  $\tau'$ , and  $\Gamma, x : \sigma \vdash e' : \tau'$ .
- If  $e = e_1(e_2)$  then there exists a type  $\tau_2$  such that  $\Gamma \vdash e_1 : \tau_2 \rightarrow \tau$  and  $\Gamma \vdash e_2 : \tau_2$ .

The proof is by inspection.

**Claim 2** (Substitution). If  $\Gamma \vdash e : \tau$  and  $\Gamma, x : \tau \vdash u : \sigma$  then  $\Gamma \vdash u[e/x] : \sigma$ .

*Proof.* By induction on the derivation of  $\Gamma, x : \tau \vdash u : \sigma$ .

Case(LAM). Suppose the derivation is of the form

$$\frac{\displaystyle \frac{\vdots}{\Gamma, x : \tau, y : \sigma_1 \vdash u : \sigma_2}}{\Gamma, x : \tau \vdash \lambda y : \sigma_1. u : \sigma_1 \rightarrow \sigma_2} \text{LAM}$$

By **weakening** we have  $\Gamma, y : \sigma_1 \vdash e : \tau$ . Then, applying the **IH** to that and the smaller derivation  $\Gamma, x : \tau, y : \sigma_1 \vdash u : \sigma_2$  we obtain a derivation of  $\Gamma, y : \sigma_1 \vdash u[e/x] : \sigma_2$ . We can then construct

$$\frac{\displaystyle \frac{\vdots}{\Gamma, y : \sigma_1 \vdash u[e/x] : \sigma_2}}{\Gamma \vdash \lambda y : \sigma_1. u[e/x] : \sigma_1 \rightarrow \sigma_2} \text{LAM}$$

But we have that  $(\lambda y : \sigma_1. u)[e/x] \stackrel{\text{def}}{=} \lambda y : \sigma_1. u[e/x]$ , so we have the result.

Case(APP). Suppose the derivation is of the form

$$\frac{\displaystyle \frac{\vdots}{\Gamma, x : \tau \vdash u_1 : \tau_2 \rightarrow \sigma} \quad \displaystyle \frac{\vdots}{\Gamma, x : \tau \vdash u_2 : \tau_2}}{\Gamma, x : \tau \vdash u_1(u_2) : \sigma} \text{APP}$$

Applying the **IH** to the smaller derivation  $\Gamma, x : \tau \vdash u_1 : \tau_2 \rightarrow \sigma$  we obtain  $\Gamma \vdash u_1[e/x] : \tau_2 \rightarrow \sigma$ .

Applying the **IH** to the smaller derivation  $\Gamma, x : \tau \vdash u_2 : \tau_2$  we obtain  $\Gamma \vdash u_2[e/x] : \tau_2$ .

We combine these two derivations using the rule **APP**:

$$\frac{\displaystyle \frac{\vdots}{\Gamma \vdash u_2[e/x] : \tau_2} \quad \displaystyle \frac{\vdots}{\Gamma \vdash u_1[e/x] : \tau_2 \rightarrow \sigma}}{\Gamma \vdash u_1[e/x](u_2[e/x]) : \sigma} \text{APP}$$

But the subject of this last derivation is by definition  $(u_1(u_2))[e/x]$ .

□

**Claim 3** (Preservation). If  $\vdash e : \tau$  and  $e \mapsto e'$  then  $\vdash e' : \tau$ .

*Proof.* By induction on  $e \mapsto e'$ .

Case(D-BETA). Suppose the reduction is of the form  $(\lambda x : \sigma. e_1)(e_2) \mapsto e_1[e_2/x]$ .

We know from the assumptions that  $\vdash (\lambda x : \sigma. e_1)(e_2) : \tau$ . By **inversion** this means that there exists  $\tau_2$  such that  $\vdash \lambda x : \sigma. e_1 : \tau_2 \rightarrow \tau$  and  $\vdash e_2 : \tau_2$ .

Again by **inversion** on the judgement  $\vdash \lambda x : \sigma. e_1 : \tau_2 \rightarrow \tau$  we see that  $\tau_2 = \sigma$ , and it must be that  $x : \sigma \vdash e_1 : \tau$ .

By **substitution** on the judgements  $x : \sigma \vdash e_1 : \tau$  and  $\vdash e_2 : \tau_2$  (recall that  $\sigma = \tau_2$ ) we get  $\vdash e_1[e_2/x] : \tau$ , which is what we wanted to prove.

Case(D-APP-1). Suppose that the reduction is the form  $e_1(e_2) \mapsto e'_1(e_2)$  with premise  $e_1 \mapsto e'_1$ .

We know from the assumptions that  $\vdash e_1(e_2) : \tau$ . By **inversion** it must be that there exists  $\tau_2$  such that  $\vdash e_1 : \tau_2 \rightarrow \tau$  and  $\vdash e_2 : \tau_2$ .

By the **IH** applied to  $\vdash e_1 : \tau_2 \rightarrow \tau$  and  $e_1 \mapsto e'_1$  we get that  $\vdash e'_1 : \tau_2 \rightarrow \tau$  as well. Thus, we can construct a typing derivation

$$\frac{\frac{\vdots}{\vdash e'_1 : \tau_2 \rightarrow \tau} \quad \frac{\vdots}{\vdash e_2 : \tau_2}}{\vdash e'_1(e_2) : \tau} \text{APP}$$

□

**Claim 4** (Canonical Forms). If  $\vdash e : \sigma \rightarrow \tau$  and  $e$  val, then  $e = \lambda x : \sigma. u$  with  $x : \sigma \vdash u : \tau$ .

The proof of the canonical forms lemma is by inspection. It is a necessary lemma for proving

**Claim 5** (Progress). If  $\vdash e : \tau$  then either  $e$  val or  $e \mapsto e'$  for some  $e'$ .

*Proof.* By induction on  $\vdash e : \tau$ .

Case(LAM). If the typing derivation ends with  $\vdash \lambda x : \sigma. e : \tau$  then by the rule VAL-LAM we immediately know that  $\lambda x : \sigma. e$  val, so we have the result.

Case(APP). Suppose the typing derivation is of the form

$$\frac{\frac{\vdots}{\vdash e_1 : \tau_2 \rightarrow \tau} \quad \frac{\vdots}{\vdash e_2 : \tau_2}}{\vdash e_1(e_2) : \tau} \text{APP}$$

for some  $\tau_2$ . Then we apply the **IH** to  $\vdash e_1 : \tau_2 \rightarrow \tau$ , which gives two cases.

- If  $e_1$  val then we know that  $\vdash e_1 : \tau_2 \rightarrow \tau$  so by the **canonical forms** lemma we see that  $e_1 = \lambda x : \tau_2. u$  for some  $u$ . Hence we can perform the reduction  $(\lambda x : \tau_2. u)(e_2) \mapsto u[e_2/x]$  by the rule D-BETA.
- If there exists  $e'_1$  with  $e_1 \mapsto e'_1$  then by the rule D-APP-1 we can perform the reduction  $e_1(e_2) \mapsto e'_1(e_2)$ .

In either case there is an available reduction we can perform on the term  $e_1(e_2)$ .
